

The report provides an overview of the system, which is based on an MVC pattern. The controller is where the action happens. The controller, in turn, uses a visitor pattern.

The algorithm used to compare code structures appears to be home-grown. It's unclear how effective this approach is because there are no benchmarks presented. It's unclear exactly what the numbers meant. What would have been better is to have a standard set and establish numbers ahead of time (by the model) and then run the experiments. As it stands now, we don't know exactly what the experiments are telling us.

Overall, a solid job.
